Access and Connection

transport choice

Overview					
Indicator name	Cycling accessibility				
Indicator number	3 Indicator type Supplementary				
Objective	To measure the connectivity, access, and quality of cycling infrastructure across the State				
Application guidance	Providing sustainable transport systems is a key indicator of sustainable cities and communities. Sustainable modes of transport serve people of all ages and abilities, and where an area is more permeable for bicycle riders, getting around by bike becomes the natural choice.				
	This indicator will support practitioners to understand the availability and accessibility of cycling infrastructure. Based on the outcome of the assessment, practitioners can determine whether additional links could be considered to enhance the connectivity of the cycling network for users.				
	Practitioners can use the <i>connected cycling network</i> metric to measure the individual or multiple components of cycling infrastructure that combine to form a connected network and the percentage of infrastructure classes that comprise that network.				
	Practitioners can use the <i>access to cycling network</i> metric to measure the distance required to travel along the road network to access a cycling specific network.				
	Practitioners can use the <i>cycling infrastructure type and length of cycling infrastructure</i> metrics to measure the desirability and extent of cycling facility, respectively.				

(0)

Metric

Metric - Connected cycling network

Metric unit	Count / percent (%)				
Description	To measure the individual or multiple components of cycling infrastructure that combine to form a connected network and the percentage of infrastructure classes that comprise that network				
Spatial coverage	NSW urban areas, subject to presence of cycling specific infrastructure				
Spatial application	This metric is most suitable for link-based analysis based on the road network				
Calculation methodology	Create cycling infrastructure buffer for spatial joining				
	1. Create 1m buffer placed around all appropriate cycling infrastructure (this is to account for poor topology within the dataset)				
	2. Dissolve the buffer data and the resulting object ID is replicated as a "Network ID"				
	Join spatially to get count and percentage				
	Buffer data with Network ID is spatially joined back to the underlying cycling infrastructure				
	4. Unique networks will be created by dissolving based on Network ID				
	5. Spatially join the unique networks to the original infrastructure dataset using 'share line segment' and in the field map sum infrastructure types				
	6. Add another field that counts individual infrastructure segments				
	7. Percentage infrastructure types can be calculated with unique network length				
	Note: The underlying network was aggregated and joined to develop class percentages which were calculated through an excel pivot table.				
Assumption	 Infrastructure classes used in this analysis include bicycle path, shared path and bicycle lane 				
	Infrastructure classes are accurate and reflect on-the-ground facilities				
	 Connections between infrastructure assets are mapped correctly 				
	 Road sections with wide shoulders are excluded from analysis as these are not considered cycling specific infrastructure 				
Limitation	 NSW Cycleways dataset is accurate as of August 2020. Changes to the cycling network that have occurred since August 2020 are not reflected in the dataset 				
	General routable network is used in the analysis, and is not enhanced for cycling journeys				
Data source	TfNSW Road Track Path Network				
	TfNSW, NSW Cycleways (August 2020)				

Metric - Access to cycling network

Metric unit	Metres (m)							
Description	To measure the distance required to travel along the road network to access a cycling specific network							
Spatial coverage	NSW Urban areas, subject to presence of cycling specific infrastructure							
Spatial application	This metric is most suitable for link-based analysis based on the road network							
Calculation	Obtain incident and faci	lity points						
methodology	1. Create road segment	mid-point with	unique ID					
	2. Create end/dangle po	ints from cyclin	ng infrastructure	with unique ID				
	3. Use mid-point as incid	dent point for n	etwork analysis					
	4. Use end/dangle points	s as facility poi	nt for network an	alysis				
	Perform network analysi	is						
	5. Conduct "closest facility" function based on network analysis (direction is from incident to facility)							
	6. Use input from Step 3 and 4 to generate routes							
	7. Extract the origin and destination ID from the routes attribute							
	8. Use origin ID to join back the route length to the road segment							
	8. Use origin ID to join b	ack the route le	ength to the road	segment				
		ack the route le	ength to the road	segment				
	Data representation			segment

Metric - Cycling infrastructure type

<u> </u>					
Metric unit	Type of infrastructure				
Description	To measure the type of cycling facility provided for users				
Spatial coverage	Applicable to all NSW				
Spatial application	This metric is most suitable for link-based analysis based on the road network and off-road cycling paths as per the NSW Cycleways dataset				
Calculation methodology	Obtain data on cycling infrastructure 1. Obtain TfNSW NSW Cycleways dataset 2. Identify infrastructure type classification and direction of travel • Bicycle path - directional • Bicycle path - non-directional • Shared path - non-directional • Shared path - non-directional • Separated path - non-directional • Bicycle lane - directional • Bicycle lane - non-directional • Bicycle paths are off-road facilities for bicycle use only • Shared paths are off-road facilities shared with pedestrians • Separated paths are off-road facilities that are separated from other vehicles by road markings (may be located between parked cars and moving traffic lanes) • Directionality means there is a direction of travel indicated for bicycle riders • Directionality improves safety outcomes for bicycle riders by reducing conflicts with other bicycle riders • Hierarchy is based on desirability of cycling facilities in terms of the outcomes for bicycle riders. Guidance on preferred facilities can be found in the Cycleway Design Toolbox, Section 2.2.1 Data representation 3. Assign colour based on the classification below Hierarchy (desirability of cycling facilities) Bicycle Path - Non Directional Shared Path - Non Directional Shared Path - Non Directional Shared Path - Non Directional Bicycle Lane - Directional Bicycle Lane - Directional				
Assumption	Infrastructure classes are accurate and reflect on-the-ground facilities				
Limitation	NSW Cycleways dataset is accurate as of August 2020. Changes to the cycling network that have occurred since August 2020 are not reflected in the dataset				
Data source	TfNSW, NSW Cycleways (August 2020)				

Metric - Length of cycling infrastructure

Metric unit	Metres (m)							
Description	To measure the length of cycling infrastructure provided for users							
Spatial coverage	Greater Sydney and NSW Outer Urban and Bounded Localities							
Spatial application	This metric is most suitable for area-based analysis based on SA2 (Greater Sydney) and Sections of State (rest of NSW)							
Calculation	Obtain data so	ources						
methodology	 Obtain boundary data from ABS, including SA2 and Sections of State for Outer Urban and Bounded Localities 							
	Calculate cycleway length							
	2. Intersect cycling facility data (lines) with the boundary data obtained in Step 1							
	 3. Spatially join the output of Step 2 to the boundaries obtained in Step 1, summing the length of cycling infrastructure using a "contains" border Data representation 4. Assign colour based on the classification below 							
								Unit: Meters
	3 - 2,500	2,501 - 5,000	5,001 - 20,000	20,001 - 75,000	75,001 - 100,000	100,001 - 150,000	150,001 - 200,000	
Assumption	Infrastructure classes are accurate and reflect on-the-ground facilities							
Limitation	Sections of State dataset does not consider location name							
	 NSW Cycleways dataset is accurate as of August 2020. Changes to the cycling network that have occurred since August 2020 are not reflected in the dataset
